ABSTRACT

BACKGROUND: Nevus spilus (NS) is a potential precursor of melanoma; the vast majority of cases reported in the literature were histologically classified as superficial spreading melanoma. OBJECTIVE: To demonstrate the diagnostic value of reflectance confocal microscopy (RCM) in this subtype of congenital nevi.

METHODS: We report a case of a large congenital NS with equivocal clinical and dermoscopic findings in which RCM was applied for diagnosis and follow-up. RESULTS: There was a good correlation of RCM with histopathology and a lack of dynamic changes during follow-up. CONCLUSION: Our observations indicate that RCM, as a non-invasive tool, can be useful for diagnosis and follow-up of clinically and dermoscopically equivocal NS.
