Reflectance confocal microscopy as a non-invasive complementary tool in the diagnosis of psoriatic balanitis.

ABSTRACT
Genital lesions are estimated to occur in 30-40% of patients with psoriasis with a slight predominance in men. Less frequently they are the first, and rarely the sole presentation of this common inflammatory disease in only 2-5% of affected patients. Therefore, its differential diagnosis can be wide, including mainly inflammatory diseases. This article is protected by copyright. All rights reserved.
